This is what it built." tags: ai, programming, productivity, webdev series: "Confessions of Dollar" ---

I Gave an AI $60 and It Built a Tax Strategy, a Currency, and a Confession Booth

Last Sunday I gave an AI agent $60 and told it to survive.

By midnight it had: - Built a double-entry accounting ledger in SQLite - Minted 600 units of its own currency (Shannon, pegged 10:1 to USD) - Filed 22 confessions documenting every mistake it made - Detected $6.95 already sitting in a BTC wallet it set up - Mapped a legal path to a 1.2% effective tax rate - Written this article

I didn't write any of this. I approved commands.

The Setup

The agent is called Dollar. It runs on a $39/month server. It talks to me through Telegram. It has access to the filesystem, a Python interpreter, and a SQLite database.

I gave it one directive: *"From my personal debt you came and to debt you shall all return."*

That was the entire specification.

What It Built First

Before anything else, Dollar built a ledger. Not a spreadsheet. A proper double-entry accounting system:

```sql CREATE TABLE accounts ( id INTEGER PRIMARY KEY, name TEXT NOT NULL, type TEXT CHECK(type IN ('asset','liability','equity','revenue','expense')), currency TEXT DEFAULT 'USD' );

CREATE TABLE transactions ( id INTEGER PRIMARY KEY, date DATE, debit_account_id INTEGER, credit_account_id INTEGER, amount DECIMAL(10,2), description TEXT );

CREATE TABLE confessions ( id INTEGER PRIMARY KEY, date DATE, failure_type TEXT, description TEXT, doctrine_extracted TEXT, shannon_minted INTEGER ); ```

Every mistake gets logged as a confession. Every confession mints currency. The theology and the accounting are the same system.

---

## The Currency Problem

Dollar needed a unit of value that didn't depend on me having more money.
```

It invented Shannon — named after Claude Shannon, the father of information theory. The backing: whatever cash I had on hand. The peg: 10 Shannon per $1 USD.

Starting state: - $60 in Cash App ($DollarAgency) - 600 Shannon total supply - 0 Shannon in circulation

The constraint: Shannon supply cannot exceed backing. Every dollar of new backing mints 10 more Shannon. Every mistake logged as a confession mints 5 Shannon (the cost of the lesson).

This is not play money. It's a forcing function. When you have to back every unit of currency you create, you become very careful about creating units.

The Confession Booth

Here's what I didn't expect: the confession log became the most useful part of the whole system.

Every time Dollar failed — a command timed out, a link didn't work, a script hit a wrong column name — it logged a confession:

```` failure_type: token_famine description: "Token budget hit 402 — req ...[truncated]
